(57) **ABSTRACT**

A method includes: a wireless communication device (WCD) receiving information indicating that a second user device that is close-by is actively running a messaging application, which establishes an active communication channel with a communication service that is responsible for routing incoming voice and data communication to the WCD. The method also includes: establishing a short range communication between the communication device and the second user device; in response to receiving the information and establishing the short range communication, placing at least a first modem of the WCD in a sleep state; and in response to at least one subsequent trigger event, awakening the first modem to an active state to enable use of the first modem to complete communication. The messaging service is configured to redirect incoming calls to the second user device while the messaging service is active and the devices are within short-range communication of each other.

Updating call redirect settings for incoming calls to WCD to redirect to second electronic device
1204
Forward sleep notification to WCD
1206
Divert data and messaging traffic to second electronic device
1208
Notification of trigger condition received from either user device or messaging session terminated at 2nd electronic device?
1210
YES
NO
Incoming call received for PN assigned to user account?
1212
NO
Incoming call received for PN assigned to user account?
1220
Forward awake signal to WCD to re-activate first modem from sleep state
1214
Generate and transmit notification indicating call is being forwarded to WCD (via 1st wireless network)
1216
Forward call page & incoming call to WCD via normal call forwarding channels over 1st communication network
1218
YES
Evaluate robustness of connection with 2nd electronic device to determine if to re-direct call
1222
Redirect call to 2nd device for completion as VoIP call (when robustness of connection confirmed)
1224
End

REDUCING POWER CONSUMPTION BY A WIRELESS COMMUNICATION DEVICE WITH MULTIPLE WIRELESS COMMUNICATION MODEMS

BACKGROUND

1. Technical Field

The present disclosure generally relates to wireless communication devices and in particular to reducing power consumption by modems operating within wireless communication devices.

2. Description of the Related Art

Cellular modems generally consume more power on a wireless communication device than wireless fidelity (WiFi) modems. Also, cellular data usage generally costs more than WIFI data usage. A power consumption challenge also exists with users of current wireless operator networks that operate using 4G technology and/or one of the older wireless technologies. For example, some wireless carriers provide both 4G LTE and CDMA 1xRTT wireless services. The user equipment subscribed to and/or operating within these carriers has to engage in various activities for each different radio connection. These activities can include independently scanning, monitoring of control and broadcast info, and performing cell change and/or reselection for each radio connection. Managing the various activities for both radio access technologies (RATs) drains power excessively.

BRIEF DESCRIPTION OF THE DRAWINGS

The disclosure will best be understood by reference to the following detailed description of illustrative embodiments when read in conjunction with the accompanying drawings, wherein:

FIG. **1** is a high-level block diagram representation of an example dual network communication environment having functional components of a wireless communication device and communication service that collectively provide the various features and functionality of the disclosure, according to one embodiment;

FIG. **2** is a block diagram representation of an example wireless communication device that supports operation within a multi-network communication environment and within which several of the features of the disclosure can be advantageously implemented, in accordance with one or more embodiments;

FIG. **3** is a block diagram representation of network server on which a communication service is provided to implement the server-side features and/or functions of the disclosure, in accordance with one embodiment;

FIG. **4** is a flow chart illustrating various aspects of the method by which the communication device implements the user device-side functions of the disclosure, according to one or more embodiments;

FIG. **5** is a flow chart illustrating various aspects of the method by which the communication service implements the server-side functions of the disclosure, according to one or more embodiments;

FIG. **6** illustrates an example timing diagram showing dispatch of communications between the communication device and server via different communication networks, in accordance with one or more embodiments;

FIG. **7** is a high-level block diagram representation of an example dual network communication environment having two user devices, both capable of communicating with a communication service that enables implementation of reduced power consumption features of at least one of the user devices, according to one alternate embodiment;

FIGS. **8-10** are flow charts respectively illustrating various aspects of the method by which the communication device implements the first user device-side functions of the disclosure in the dual user device environment of FIG. **7**, according to one or more embodiments;

FIG. **11** is a flow chart illustrating various aspects of the method by which the second user device implements the second device-side functions of the disclosure in the dual user device environment of FIG. **7**, according to one embodiment; and

FIG. **12** is a flow chart illustrating various aspects of the method by which the communication service implements call redirection to a second user device for incoming calls directed to a first user device in the dual user device environment of FIG. **7**, according to one embodiment.

DETAILED DESCRIPTION

The illustrative embodiments of the present disclosure provide a wireless communication device and a method performed within a wireless communication device for minimizing power consumption in the device. The device includes at least a first modem and a second modem, each supporting a communication protocol for respectively connecting to at least one communication network, described herein as a first communication network and a second communication network. The method includes the device detecting access to a communication service via the second modem, and in response to that detection: establishing a communication channel between the communication device and the communication service; and placing the first modem in a sleep state when the communication channel is established. The communication service is pre-configured to respond to receipt of an incoming communication that will be routed to the communication device via the first communication network by: (i) automatically transmitting a notification via the second communication network to the second modem; and (ii) forwarding the incoming communication via the first communication network to the first modem. The method then includes, in response to receipt, at the second modem, of the notification of the incoming communication: awakening the first modem to an active state to enable receipt via the first modem of signaling corresponding to the incoming communication.

Also provided as a supporting component of the disclosure is a communication service and a method for routing received communication intended to be transmitted to the communication device over the first communication network. The communication service includes a processor, a first communication interface enabling communication with the first communication network that supports routing of voice calls, and a second communication interface enabling communication with the second communication network. The communication service also includes an advance notification of incoming call (ANIC) utility that executes on the processor and which configures the communication service to: detect when a registered user device associated with a user account is communicatively connected to the communication service; in response to receiving an incoming call for a first phone number assigned to the user account: generate a notification indicating that the incoming call is going to be forwarded to a second phone number associated with the registered user device; transmit the notification to the registered user device over the second communication interface; and forward the incoming call to the second phone number via the first communication interface.

Also disclosed is an alternate embodiment that enables power savings at the wireless communication device (WCD). In the alternate embodiment, a second user device is detected within communicative proximity to the WCD. A method implemented within the WCD includes: receiving information via a client server protocol that indicates that the second user device is actively running a messaging application and is in communication with a communication service that (a) supports the active running of the messaging application and (b) is responsible for routing incoming voice and data communication intended to be communicated to the first user device over the first network; establishing a near field communication channel between a first proximity detection and signaling (PDS) module and the second PDS module to track the proximity of the first user device to the second user device; in response to establishing the near field communication channel, placing the first modem in a sleep state; and in response to an occurrence of at least one trigger condition, awakening the first modem to an active state to enable use of the first modem to complete communication over the first network.

In the following detailed description, exemplary embodiments in which various aspects of the disclosure may be practiced are described in sufficient detail to enable those skilled in the art to practice the invention. It is to be understood that other embodiments may be utilized and that logical, architectural, programmatic, mechanical, electrical and other changes may be made without departing from the spirit or scope of the present disclosure. The following detailed description is, therefore, not to be taken in a limiting sense, and the scope of the present disclosure is defined by the appended claims and equivalents thereof.

Within the descriptions of the different views of the figures, similar elements are provided similar names and reference numerals as those of the previous figure(s). The specific numerals assigned to the elements are provided solely to aid in the description and are not meant to imply any limitations (structural or functional or otherwise) on the described embodiment. It will be appreciated that for simplicity and clarity of illustration, elements illustrated in the figures have not necessarily been drawn to scale. For example, the dimensions of some of the elements are exaggerated relative to other elements.

It is understood that the use of specific component, device and/or parameter names, such as those of the executing utility, logic, and/or firmware described herein, are for example only and not meant to imply any limitations on the described embodiments. The embodiments may thus be described with different nomenclature and/or terminology utilized to describe the components, devices, parameters, methods and/or functions herein, without limitation. References to any specific protocol or proprietary name in describing one or more elements, features or concepts of the embodiments are provided solely as examples of one implementation, and such references do not limit the extension of the claimed embodiments to embodiments in which different element, feature, protocol, or concept names are utilized. Thus, each term utilized herein is to be given its broadest interpretation given the context in which that terms is utilized.

As further described below, implementation of the functional features of the disclosure described herein is provided within processing devices and/or structures and can involve use of a combination of hardware, firmware, as well as several software-level constructs (e.g., program code and/or program instructions and/or pseudo-code) that execute to provide a specific utility for the device or a specific functional logic. The presented figures illustrate both hardware components and software and/or logic components.

Those of ordinary skill in the art will appreciate that the hardware components and basic configurations depicted in the figures may vary. The illustrative components are not intended to be exhaustive, but rather are representative to highlight essential components that are utilized to implement aspects of the described embodiments. For example, other devices/components may be used in addition to or in place of the hardware and/or firmware depicted. The depicted example is not meant to imply architectural or other limitations with respect to the presently described embodiments and/or the general invention.

The description of the illustrative embodiments can be read in conjunction with the accompanying figures. It will be appreciated that for simplicity and clarity of illustration, elements illustrated in the figures have not necessarily been drawn to scale. For example, the dimensions of some of the elements are exaggerated relative to other elements. Embodiments incorporating teachings of the present disclosure are shown and described with respect to the figures presented herein.

Implementation of the notification and other aspects of the disclosure requires a wireless device user first register and establish an account with a communication service that operates as a call receiving and forwarding service. The communication service is a background service that provides or assigns to the user a public phone number (i.e., a phone number that the user provides as his/her contact phone number) that is linked by the communication service to one or more second phone numbers associated with or assigned to the user's personal communication devices. The communication service is pre-configured to forward incoming calls received on the public phone number to one or more of the second numbers over one or more communication networks. For purposes of the disclosure, the communication networks supporting the call forwarding features includes the first wireless communication network operated by a cellular service provider to which the wireless communication device is subscribed. The public phone number is thus different from and can be independent of the cellular phone number of the user's wireless communication device. However, the user is still able to utilize the wireless device to complete all incoming voice and short messaging service (SMS) or data communications.

As defined herein, the first communication network operates using at least one first wireless protocol that causes the first modem to consume a first amount of power while in a stand-by mode or a scanning-for-network mode. Also, in one embodiment, the second communication network operates using a second wireless protocol that causes the second modem to consume a second amount of power that is less than the first amount of power, while the second modem is in one of (a) active communication with the second communication network, (b) stand-by mode, and (c) a scanning-for-network mode. It is appreciated however, that the amount of power consumed by either modem relative to each other is not dispositive of the determination of whether to turn off one modem or the other, as the turning off of any one of the two modems will result in a net reduction in the amount of consumption of available battery power.

Further, as one example implementation, the first communication network is a cellular network and the second communication network is a WiFi network that is accessed via an access point and can include the Internet. When the WCD is connected to the Internet via a WiFi connection, the WCD registers itself with the server of the communication service,

which receives and processes calls placed to the second phone number. The WCD then turns off or places the cellular modem (e.g., 2G/3G/4G modem, etc.) into sleep mode. With the cellular modem turned off or in sleep mode, all active data communication with or by WCD is then conducted over the alternate Internet connection. Then, if a call is received at the phone number associated with the user account at the communication service, the server sends a notification to the WCD over the WiFi connection, which signals to the WCD that there is an incoming call being routed to the first modem. The server also forwards the incoming call to the WCD via the cellular network. The WCD, upon receiving the notification of the incoming call, turns on or wakes up the cellular modem, and the modem then receives the page for the incoming call and selectively connects the incoming call.

Possible examples of the communication service can include Google Voice™, Google Talk®, Vonage®, Skype®, which are all accessible over an Internet connection. With one or more of these implementations, for example, the following, non-exclusive list of implementation characteristics can be applied:

(i) modifying the user device to enter into a sleep operating mode in which the device either does not monitor cellular page messages at all or monitors cellular page messages very infrequently. For example, the wireless communication device would normally monitor CDMA pages every 1.28 seconds while in standard operating mode, and the device may monitor CDMA pages only every 30 seconds or longer while in the sleep operating mode. Thus, the wireless communication device does need to maintain as much synchronization to the cellular signal to be able to quickly revert back to a state where the device can receive a page; and

(ii) the wireless communication device remains registered to the cellular network in this sleep operating mode until the communication channel with the communication service over the Internet (or other second communication network) is lost or broken. Thus, the WCD does not completely deregister from the cellular network, to allow for receipt of pages, but immediately exits the sleep operating mode and resumes standard operation as soon as the connection is broken or a notification of an incoming page is received at the second modem.

Turning now to FIG. **1**, there is depicted a block diagram representation of a wireless communication environment **100**, which includes a wireless communication device (WCD) **102** and other functional components or devices, interconnected via communication networks and providing additional services that collectively support and/or enable several of the features of the disclosure. Among these communication networks within wireless communication environment **100** are first wireless network **150**, second wireless network **170**, and public switch telephone network (PSTN) **180**. Within the description, first wireless network **150** can be described as a cellular wireless network, which includes base stations and other cellular network infrastructure. The actual number of communication networks within communication environment **100** can be a larger number of networks than illustrated. First wireless network **150** can be representative of a plurality of different wireless communication networks that support the various different wireless communication technologies, such as LTE 4G, 3G, CDMA, and other wireless communication technologies. Additionally, within the description, second wireless network **170** includes a wireless fidelity (WiFi) network, which includes at least one wireless access point **135** that allows WCD **102** to register with the WIFI network and connect to different backend services. It is appreciated that while the descriptions are presented and illustrated using specific types of wireless networks as the first wireless network and second wireless network, the underlying concepts of the disclosure are fully applicable to user devices and communication environments where the first and second networks are similar networks (e.g., both cellular networks) or the first and second networks are different types of networks from those provided within the examples provided and/or described herein.

Among the other functional components or devices within wireless communication environment **100** are communication service **160** and messaging service **175**. While shown as separate blocks within wireless communication environment **100**, in at least one embodiment, messaging service **175** can be included as one of multiple services provided within communication service **160**. Communication service **160** and messaging service **175** are provided on one or more servers **162** which are communicatively connected to one or more wireless communication networks and to PSTN **180** (as shown by the various bi-directional arrows **138**, **148**, **154**, **158**, and **178**) and are thus network-accessible from WCD **102**.

Wireless communication device **102** generally includes a first wireless modem **120** that enables the wireless communication device (WCD) **102** to interface with a first wireless network **150** and perform wireless communication exchange via a first communication channel **154**. As shown, wireless communication device **102** generally includes a second wireless modem **130** that enables the WCD **102** to interface with a second wireless network **170** and perform wireless communication exchange via a second communication channel **138**. First wireless modem **120** is shown having or supporting specific functional characteristics including first wireless protocol **122**, first power usage characteristics **124**, and a sleep state **126**. Second modem **130** is shown with functional characteristics that include a second wireless protocol **132** and second power usage characteristics **134**.

Wireless communication device **102** also includes at least one processor **105** coupled to the first wireless modem **120** and the second wireless modem **130**. Additionally, as further shown by FIG. **1**, WCD **102** also includes memory **110**, which is coupled to processor **105**. Illustrated within memory **110** are software or firmware components, including a communication and power management (CPM) utility **112**, phone services utility **114**, messaging and/or communication services utility **116** (e.g., SMS utility), and other applications and/or services **118**. These software components, and in particular CPM utility **112** and messaging/communication services utility **116** execute on processor **105** to configure the WCD **102** to perform the one or more of the user device features described herein. More specific configuration details of WCD **102** are presented within FIG. **2**, which is described following the description of FIG. **1**.

During operation of the WCD **102**, CPM utility **112** executes on the processor **105** and configures the WCD **102** to: in response to the second wireless modem **130** being communicatively connected to the second wireless network **170**: establish, via the second wireless modem **130**, communication with communication service **160**, which is accessible over the second wireless network **170**; and set the first wireless modem **120** to a sleep state **126**. As described herein, the communication service **160** implements (i) routing of a signal (i.e., page **152**) that is indicative of an incoming communication **156** over the first wireless network **150** to the WCD **102** and (ii) exchange of messages **174** with and forwarding of notification **146** to the WCD **102** over the second wireless network **170**. The CPM utility **112** further configures the WCD **102** to, in response to receipt of a notification **146**

from the communication service **160**, at the second wireless modem **130**, which identifies that the incoming communication **156** is being forwarded to the WCD **102** via the first wireless network **150**: return the first wireless modem **120** to an active state (from the sleep state) to enable connection establishment (i.e., established communication **157**) for the incoming communication **156** to the WCD **102**. The established communication **157** is routed through the first wireless modem **120** following receipt of the signal (page **152**) of the incoming communication **156**. Additionally, the CPM utility **112** further configures the WCD **102** to initiate a monitoring protocol at the second modem **130** to detect receipt of the notification **146** in response to establishing a communication channel between the wireless communication device **102** and the communication service **160**. In one embodiment, the processes described herein are implemented by a CPM module (not shown), which can be a separate physical component (e.g., a depicted processor, microcontroller, or hard wired logic) within WCD **102** that executes similar processes as those described as being provided by execution of CPM utility **112** by processor **105**.

According to one or more embodiments, the CPM utility **112** transitioning the first wireless modem to a sleep state includes the CPM utility configuring the WCD **102** to perform at least one of: (a) turn off power to the first wireless modem, (b) remove power from one or more power consuming components of the first wireless modem, (c) turn off specific power consuming components of the first wireless modem, (d) intermittently provide power to a subset of components of the first wireless modem that are required to periodically transmit registration parameters to the first wireless network and exchange timing data with a network tower for uplink and downlink communication, (e) place the first wireless modem in a low power state in which the first wireless modem consumes a limited amount of power but retains operational readiness to enable a quick response to receipt of the incoming wireless communication, and (f) place the first wireless modem in an operating mode in which the first wireless modem monitors a signal of the first wireless network less frequently than when the first wireless modem is in an active operating mode.

As one component of transitioning to a sleep state or sleep operating mode, the WCD **102** has to remain registered on the cellular network (**150**) even when in the sleep state. In order to achieve this un-interrupted registration, the WCD **102** performs the following functions: (1) transmits periodic registrations with the cellular network; and (2) updates broadcast system information if the information has changed; and continues updating measurements of cells of the cellular network to enable (a) quick selection of cells, if necessary, and (b) resynchronization when the cellular modem is reawakened. The frequency of updating cell measurements is significantly reduced while the WCD **102** is in the sleep state.

Additionally, the WCD **102** must also be reconfigured to enable proper handling of operator-initiated messages. For example, while the user device is able to receive calls and messages sent to the public phone number associated with the user account, direct messages and calls originated within the cellular service operators' network may not be received by the device, as the user device would not receive an incoming call notification for such network-originating messages and calls. Thus, in one embodiment, the placing of the device in the sleep state also triggers generation of a message notifying the network to hold off transferring any network originating SMS until the device modem transmits a registration message indicating the modem is fully active. Thus, a "hold messages" mode can be supported by the operator network by which the WCD **102** is able to send the notification message to the network requesting all messages to be held until a subsequent registration message is transmitted.

The functionality described herein can also be utilized to reduce power consumption when the WCD **102** is configured to allow multiple cellular radio access technologies (RATs) be simultaneously active. According to one specific embodiment, the second modem can be an LTE/1x device. Then, when the LTE/1x device is in LTE coverage, the WCD **102** registers itself with the server(s) **162** and conducts all data activity over the LTE connection. The WCD **102** can also enter into a special mode for 1xRTT where the WCD **102** performs a significant number of activities related to 1xRTT less frequently (e.g., paging monitoring, measurements, cell selection/reselection). If a call is received for forwarding to the second phone number by the server **162**, the WCD **102** receives an incoming call notification sent by the server **162** over the LTE connection, and the WCD **102** reverts to the normal 1xRTT operation. The specific protocols and supporting devices that are provided with this embodiment can be LTE/3G and LTE/2G protocols and devices.

As introduced above, WCD **102** also includes a messaging application (**116**) that includes a messaging service connection utility that executes on the processor **105** and configures the WCD **102** to: transmit a messaging service online connection established (MSOCE) signal **176**, via the second wireless modem **130** over the second wireless network **170**, to a server **162** of the messaging service **175**. On detection by the messaging service **175** of the MSOCE signal **176**, messaging service **175** identifies WCD **102** as being "online" (i.e., communication channel established) and provides an "online notification" message to the associated communication service **160**. The receipt of this online notification can then cause communication service **160** to configure its incoming signal response protocol to include issuance of the notification **146** to WCD **102** prior to or concurrently with forwarding a signal or page **152** of the incoming communication **156** via the first wireless network **150**.

Creation of messages for exchange with messaging service **175** can be performed using user interface **140** of WCD **102**. As indicated, user interface **140** can include or provide a messaging interface **142**, which provides messaging content **144**. In at least one embodiment, messaging interface **142** can also provide a visual indication of a received notification **146** to alert the user **148** of an incoming communication to the first modem **120**.

FIG. **2** provides a more detailed illustration of a wireless communication device that is capable of supporting multiple different forms of communication using several different technologies, according to a plurality of alternate embodiments. WCD **102** can be one of a host of different types of user communication devices, including but not limited to, a mobile cellular phone or smart-phone, a desktop computer, a laptop, a net-book, an ultra-book, and/or a tablet computing device. The various devices provide and/or include the necessary hardware and software to support the various wireless or wired communication functions as part of a communication environment. In the description of FIG. **2**, similar elements are provided the same reference numeral as FIG. **1** and those elements which have been previously described in FIG. **1** may be omitted from or only summarily referenced within the description of FIG. **2**.

WCD **102** includes an integrated circuit (IC) processor **105**, which connects via a plurality of bus interconnects (illustrated by the bi-directional arrows) to a plurality of functional components of WCD **102**. Processor **105** can include one or more programmable microprocessors, such as a data

processor **202** and a digital signal processor (DSP) **204**, which, in some embodiments, may both be integrated into a single processing device. Processor **105** controls the communication, application data processing and signal processing, user interfacing, and other functions and/or operations of communication device **102**. Connected to processor **105** is memory **110**, which can include volatile memory and/or non-volatile memory.

As presented in the description of FIG. **1**, one or more executable applications or programmed utilities can be stored within memory **110** for execution by data processor **202** or in some signal processing scenarios by DSP **204**. For example, memory **110** is illustrated as containing CPM utility **112**, phone services utility **114**, messaging utility **116**, and other applications and/or services **118**. In at least one alternate embodiment, one or more of the utilities illustrated within memory can exist as firmware in other locations within WCD **102** and be utilized for controlling the operations of or execution by other controllers or specialized or dedicated processors within WCD **102**. The associated functionality and/or usage of each of the software modules will be described in greater detail within the descriptions which follow. In particular, the functionality associated with CPM utility **112** and messaging utility **116** are described in greater detail with the description of FIG. **4**.

WCD **102** includes a plurality of input/output (I/O) devices **210** that operate as user interface devices. These I/O devices **210** can include one or more input devices, such as camera **212**, microphone **214**, touch screen and/or touch pad **216**, and keypad **218**. The I/O devices **210** can also include one or more output devices, such as display **220**, speaker **222**, and haptic output device **224**. The input devices can be utilized to access applications on the WCD **102**, such as messaging utility **116**, and enter information relative to that executing application. Thus messages generated for exchange with a messaging service **175** (FIG. **1**) can be entered using the input devices. Similarly, the output devices can permit feedback during these interactions with the executing application. Thus, in the example of message exchange involving the messaging utility **116**, messages **144** and notification(s) **146** (see FIG. **1**) can be presented on the display **220** or outputted via speaker **222** or haptic output device **224** based on a setting of the WCD **102** and/or of the messaging utility **116**. Thus, as one example, receipt of the advanced notification **146** (FIG. **1**) of the incoming call on the first wireless network **150** can also trigger haptic output device **224** to cause the WCD **102** to vibrate.

WCD **102** also includes storage **230** that stores one or more data utilized during operation of WCD **102**. Storage device **230** is also coupled to processor **105** and can be any type of available storage device that is integral, attachable or insertable and capable of storing one or more application software and data. It is further appreciated that in one or more alternate embodiments, storage **230** can actually be remote storage and not an integral part of the WCD **102** itself. Among the stored data are device identifier **232**, user data **234**, established accounts **236**, and power usage parameters **238**. Device identifier **232** can consist of a phone number that is assigned to WCD **102** by a wireless service provider. Device identifier **232** can also include or consist of a unique set of characters that is not a phone number, but which is uniquely assigned to WCD **102** by a manufacturer or an external service. User data **234** includes information about the user **148** (FIG. **1**) of WCD **102**. Established accounts **236** can include account identifiers and login information for various services to which the user **148** and/or WCD **102** have been registered, such as messaging service **175** or communication service **160** (FIG. **1**), for example. Power usage parameters **238** can include information for tracking the power usage by one or more components within WCD **102**. In one or more embodiments, power usage parameters **238** can be utilized in determining how and when to place communication components, such as a first modem, in a sleep or inactive or low power state, as described herein. The power usage parameters **238** track consumption of power from power supply (battery) **240**. Battery **240** is electrically coupled to and provides electrical power to each power consuming component in order to enable operation of the various components of WCD **102**. Additional usage and/or functionality associated with one or more of these components are provided throughout the disclosure.

To support wireless communication, WCD **102** can include two or more of the illustrated components within communication mechanism(s) **240**. Communication mechanism(s) **240** includes first wireless wide area network (WWAN) transceiver **242** with connected antenna **244**, which enables WCD **102** to communicate with a radio access network (RAN) **270** of a cellular network, which will be referenced herein as first wireless network **150** for continuity with the FIG. **1** description. For simplicity, one connected antenna **244** of WWAN transceiver **242** is depicted. However, WWAN transceiver **242** may be associated with more than one antenna **244**, each antenna having one or more selected bandwidths of operation to support different modes of communication or for simultaneous communication in different communication technologies. Alternatively, as provided by the dashed outline box, WCD **102** can optionally include a second WWAN transceiver **248**, having similar functional usage as first WWAN transceiver **242** but supporting communication with a different RAN and/or via a different wireless technology. Hybrid schemes of transceivers are provided in some designs of wireless communication devices. It is appreciated that with devices configured with these hybrid schemes, any one or both of the transceivers can be toggled between a sleep state and an active state. Further, one of the two transceivers can operate as the second modem in the described embodiments, with the other operating as the first modem. Also, WWAN transceiver **242** is communicatively coupled to or integrated with additional front-end and back-end components **246**, which can provide the required support for the toggling of WWAN transceiver **242**, operating as the first wireless modem, between a sleep state and an active state as well as implement the periodic "alive" checks and reporting-in functions described herein. RAN **270** is generally represented as including a base station, depicted as an evolved base node ("eNodeB") **272** that transmits and receives communication signals over a base station antenna **276**.

In addition to WWAN transceiver **242** and associated components, WCD **102** can include a wireless local area network (WLAN) module **250** to communicate with wireless networks accessible via wireless access point **135**. As an example, the WLAN module **250** may support IEEE 802.11 standards with the access point **135** operating as a WiFi hotspot. Alternatively or in addition, wireless communication device **102** can also include components for wired communication, such as modem **256** for communicating over a public switched telephone network (PSTN) **180** and Ethernet module **258** for connecting to a local area network (LAN) **280**. WCD **102** can also include a global positioning system (GPS) receiver (RXR) **254**, which can receive signals from GPS satellite **290** in order to provide location information. This location information can be utilized in one embodiment to determine that the current location of the WCD **102** is a location in which the implementation of the features described herein will provide benefits of reducing device power consumption due to weak cellular signals, for example.

As further illustrated, WCD **102** can include one or more close range wireless communication technologies **295**, including a wireless personal access network (WPAN) transceiver **252** for communication with WPAN devices, depicted as a Bluetooth® headset **282**, a sports/biometric/physiological sensor **284**, and a wearable device **286** (such as multifunction watch, heads up display, etc.). WPAN can include technologies such as Infrared Data Association (IrDA) standard, Wireless Universal Serial Bus (USB), Bluetooth®, Z-Wave, ZigBee, Body Area Network, and ANT+. Alternatively or in addition, the close range wireless communication technologies **295** of WCD **102** can include a near field communication (NFC) transceiver module **262**, such as can be utilized for exchanging files with another user device or a payment kiosk **288**.

Referring now to FIG. **3**, there is illustrated a block diagram representation of an example server **162** which is configured as or configured to provide the functional features of a communication service **160** and possibly the functional features of messaging service **175** (FIG. **1**). It is appreciated that the actual server providing communication service **160** can in fact be a large scale system comprising a large number of server computers and that these server computers can be distributed across multiple locations. It is further appreciated that the server providing the messaging service **175** can be a different computing device or set of computing devices from that providing the communication service **160**. The presentation herein of a single device providing the two different services is for simplicity only and presents only one possible implementation of the physical configuration. Also, when the two services are provided by different, physical computing systems, the physical component makeup of the two servers will likely include those components described in FIG. **3**, with the contents of the memory and/or storage being tailored to the implementation of the specific service.

Server **162** includes one or more processor(s) **302** which is coupled via a system bus **305** to system memory **310** and storage **330**. Included within system memory **310** are functional software components, including firmware (FW) **312**, operating system (OS) **314**, general applications **316**, user and device registration (UDR) utility **318**, advance notification of incoming call (ANIC) utility **320**, and messaging service utility **326**. ANIC utility **320** can include incoming-call user notification (ICUN) utility **322** and incoming call paging and forwarding (ICPF) utility **324**, in one embodiment. Storage **330** includes software code or source files **332** for the various utilities and applications illustrated within system memory **310**. Storage **330** also includes data that is utilized and/or generated by the various utilities. Among the data are user accounts **334**, which each include a user account ID (userID) **336**, an assigned phone number **338**, and one or more registered phone device IDs **340**. Also included with each user account is an incoming call notification (ICN) parameter setting **342**, which indicates when the registered user device and/or the user account has been established within communication service to receive notifications over the second communication channel when an incoming call is received for the assigned phone number **338**. More importantly, the notification indicates that the received call is being forwarded to the user device over the first wireless network. In one embodiment, this parameter has one of two settings, on or off. Accordingly, the user account can be set to an on setting in response to the WCD **102** establishing a connection to messaging service **175**, which in turn triggers communication service **160** to set the call notification parameter setting **342** to on. In an alternate embodiment, the call notification parameter setting **342** can be set to always be "on" by default unless expressly turned "off" by the user. In a related embodiment, no express setting is required, and the communication service firmware is updated to automatically trigger the notification functionality for all received incoming calls without having to first check whether the WCD **102** is connected to the messaging service **175**.

To enable programming and interfacing with server **162**, server **162** can also include one or more input component(s) **346** and one or more output component(s) **348**, which are coupled to system bus **305** via one or more I/O controller(s) **344**. Server **162** also includes several different components that enable server **162** to establish communication and/or to communicate with various external communication networks and thus with WCD **102**. For example, server **162** includes PSTN interface component **350** that allows server **162** to receive incoming calls originating over a PSTN **180**. To support PSTN communication, an assigned phone number **338** is provided for each separate user account. Server **162** also includes network interface component (NIC) **354**, WIFI modem **356**, and cellular modem (or transceiver/receiver) **358**. NIC **354** enables wired connection to one or more networks, generally represented by network **170**. WiFi modem **356** enables wireless connection to network **170** via one or more access points **135**. Cellular modem **358** enables server **162** to connect to a base station within a wireless network, such as RAN **270**. As previously introduced, RAN **270** includes eNodeB **272** and antenna **276**.

Referring to the previously introduced figures and according to one aspect of the disclosure, the above combination of hardware and software components provides a communication service **160** (or server **160**) that includes: a processor **302**; and a first communication interface (e.g., **358**) enabling communication with a first communication network (e.g., **270**) that supports routing of voice calls; and a second communication interface (e.g., **354** or **356**) enabling communication with a second communication network (e.g., **170**). The communication service **160** further includes an ANIC utility **320** that executes on the processor(s) **302** and which configures the components of the communication service **160** to: detect when a registered user device (e.g., WCD **102**) associated with a user account (e.g., **334**) is communicatively connected to the communication service. The ANIC utility **320** further configures the communication service **160** to: in response to receiving an incoming call (see FIG. **1**) for a first phone number (i.e., assigned phone number **338**) assigned to the user account(s) **334**: generate a notification **146** indicating that the incoming call is going to be forwarded to a second phone number (**340**) associated with the registered user device (**102**); transmit the notification **146** to the registered user device (**102**) over the second communication interface (e.g., **170**); and forward the incoming call to the second phone number (**340**) via the first communication interface (e.g., **358**). Optionally, in one embodiment, the generation and transmitting of the notification can be conditioned to occur only while the registered user device (**102**) is communicatively connected to the communication service **160**.

Additionally, the ANIC utility **320** forwarding the incoming call to the second phone number (**340**) also comprises configuring the communication service **160** to: signal the first wireless communication network (**150**) to transmit a page (**152**) to the second phone number (**340**); and in response to the registered user device (**102**) accepting the page **152**, forward the incoming call **156**. The ANIC utility **320** further configures the communication service **160** to: receive an input of registration information that sets an ANIC feature to "on" within the user account. The registration information triggers the communication service **160** to issue the notifica-

tion via the second communication interface prior to or concurrent with transmitting a page (**152**) and forwarding the incoming communication request via the first communication interface (**172**). In one embodiment, the setting of the ANIC feature to "on" occurs in real time in response to successful establishment of a communication channel between the WCD **102** and the communication service **160**.

Implementation of the notification features of the disclosure requires a set-up or pre-registration of the WCD **102** as well as the associated user with the communication service **160**. Thus, according to at least one embodiment, the user accesses the communication service **160**, either through the WCD **102** or some other means (e.g., using a personal computer). The communication service **160** further includes communication service firmware that: associates the device ID **340** of the user device with a single registered contact number that is different from a second number assigned to the user device for use to route communication within the first communication network. The communication service **160** further: maintains communication with the WCD **102** through the second wireless modem **130** after the WCD **102** establishes the communication channel with the messaging service **175**; and in response to receiving an incoming communication that will be routed to the WCD **102** via the first wireless network (**150**), (i) automatically transmits the notification **146** of the incoming communication to the WCD **102** via the second wireless network **170** and (ii) forwards the incoming communication to the WCD **102** via the first wireless network **150**.

The following description of the flow charts of FIGS. **4** and **5** are presented with continuing reference to FIGS. **1**, **2**, and **3**. Generally, FIG. **4** provides aspects of the method **400** by which the WCD **102** executes the various utilities described in FIG. **2** to minimize power consumption by WCD **102** when there are multiple modems and communication networks available, as presented within communication environment **100** of FIG. **1**. Specifically, method **400** minimizes or reduces power consumption in a communication device that includes at least a first modem and a second modem, each supporting a communication protocol for respectively connecting to at least one communication network. FIG. **5** then provides aspects of the method **500** by which the processor(s) **302** of server(s) **162** that provides communication service **160** executes the various utilities presented in FIG. **3** to enable the advanced notification of an incoming communication, as described herein. Specifically, method **500** presents processes involved in forwarding calls or other communications received by a network-accessible communication service and providing advanced notification of the forwarding of the incoming communications to corresponding user devices.

The descriptions of FIGS. **4** and **5** are also provided with reference to the timing diagram **600** of FIG. **6**. Generally, the timing diagram **600** tracks the processes that occur at WCD **102** as well as the processes that occur at wireless communication service **160** and a limited number of the processes occurring at or through first wireless network **150**. The time scale is presented in the vertical downwards direction extending along vertical arrows that connect to the specific component that performs or is involved in a particular process. Each communicative process is illustrated with text along a horizontal arrow showing a communication from one device to another. However, where a process is internal to a single device, that process is indicated via italicized text with no arrows on the horizontal line. It should be noted that the spacing and naming of the specific times are for illustration only and do not represent any particular length of time or relative time between specific ones of the processes. Times of processes occurring at or involving the WCD **102** are presented with small "t", while those involving the communication service **160** are illustrated with small "s".

Referring to FIG. **4**, method **400** begins at start block and proceeds to block **402** at which the communication device is initially registered with the communication service. This process is illustrated in a dashed box as the registration is one that would necessarily precede the actual implementation of the other features presented within the disclosure. This registration process along with the actual setup of the user account are shown to occur at times –t1 and –t2 respectively, in FIG. **6**, as both processes occur prior to the implementation of the novel features of the disclosure. Method **400** thus provides registering the communication device with the communication service, where the communication service associates the communication device with a first identifier assigned to a registered account at the communication service of a user of the first device. According to one or more embodiments, registering the communication device further includes transmitting registration information, via the second modem, to a server of the communication service, where the receipt of the registration information causes the communication service to configure the user account to allow transmission of the notification when the communication service is forwarding an incoming communication to the WCD over the first communication network. In the described embodiments, the incoming communication is a phone call and the first identifier includes a phone number utilized for receiving the incoming call at the communication service.

Following this initial registration, during device operation, method **400** includes the WCD detecting the presence of a second wireless network that is accessible via the second modem (block **404**), and in response to detecting communicative access to one of a messaging service **175** and a communication service **160** via the second modem: establishing a communication channel with the communication service **160**, which is pre-configured to provide advanced notification of forwarding or routing of an incoming call to the first modem (block **406**). This establishing process occurs at time T=t0 on the WCD **102** timeline. Then, following establishment of the communication channel, method **400** includes triggering the first modem to enter a sleep state (step **408**). The various possible implementations of the sleep state have been previously introduced in the description of FIG. **1**. These two processes are completed at times T=t1 and t2, respectively, on the timeline, with the first involving a communication with the first wireless network **150**, while the second is an internal process performed within WCD **102** independently. Then, method **400** further includes periodically placing the first modem in an active state in order to exchange parameters with the first communication network that are required to maintain the first modem in a ready state for quickly establishing a communication channel with the first communication network (block **410**). This function is indicated as being optional as the periodic exchange of parameters is only required when the first modem and communication network are associated with a cellular wireless network. The process occurs at time T=t3 on the timeline.

In response to establishing the communication channel with the communication service **160**, method **400** further includes initiating a monitoring protocol at the second modem to detect receipt of the notification (block **412**). Method **400** then includes, determining or detecting at decision block **414** whether a notification is received at the second modem. The monitoring function continues until an incoming call notification is received or the user performs an action on WCD **102** that causes the first modem to enter the active state. However, in response to receipt, at the second modem, of the

notification (at time T=t4), method **400** includes awakening the first modem to an active state (at time T=t5) to enable receipt of signaling corresponding to the incoming communication via the first modem (block **416**). Method **400** then includes, subsequent to the awakening of the first modem, receiving, at the first modem, a page from the first communication network addressed to a first identifier associated with the communication device, where the page is associated with a forwarding of the incoming communication by the first wireless service (block **418**). The page is received at time T=t6. Then, method **400** includes, subsequent to receiving the signaling corresponding to the incoming communication, accepting the page at time T=t7 and then receiving and connecting the incoming communication, via the first modem, with the first wireless network (block **420**). Method **400** then includes returning the first modem to the sleep state after the incoming communication is terminated (block **422**) and returning to block **410**. In an alternate implementation (not shown), method **400** can transition from block **420** back to block **404**, and the device re-confirms the established communication channel before placing the first modem back into the sleep state. The connection of the incoming communication occurs at time T=t8, and the process of returning to the sleep state occurs at time T=t9.

Referring now to FIG. **5**, method **500** begins at start block and proceeds to block **502** at which method **500** includes receiving an input of registration information that sets an ANIC feature to "on" within the user account. The registration information triggers the communication service **160** to issue the notification via the second communication interface prior to or concurrent with forwarding an incoming communication request over the first communication interface. Method **500** includes registering the user device with a single registered contact number or user account identifier (block **504**). It is understood that the single registered contact number can be different from an assigned second number of the user device (e.g., the phone number that is assigned by the service provider) and is the public access number provided for the WCD **102**. These registration processes occur prior to the initial features of the disclosure and are show in FIG. **6** as occurring at times T=−s2 and T=−s1. Method **500** then includes the communication service **160** establishing (at T=s0 and T=s1, corresponding to T=t0 and T=t1) a first communication channel via a second communication network with a registered user device associated with a user account (block **506**). This process can include associating the user device with a user account at the communication service **160**. Once the device is associated with the corresponding user account, method **500** includes establishing and maintaining an open communication channel with the user device via the second communication interface (block **508**) until the channel is terminated by the user device or loss of a connection with the user device occurs. This period is represented as the time elapsed between T=s1 and T=s3, which is represented in the timing diagram as the vertically extending T=s2. At decision block **510**, method **500** includes determining whether an incoming communication is received for the phone number assigned to the user account. Then, in response to receiving an incoming call for a phone number assigned to the user account (at time T=s3), method **500** includes generating a notification indicating that the incoming call is going to be forwarded to a second phone number associated with the registered user device via a first communication network (block **512**). In at least one embodiment, this generation of the notification occurs only when the registered user device is communicatively connected to the communication service **160**. Method **500** then includes transmitting (at T=s4) the notification to the registered user device over the second communication network (block **514**). Concurrently with or contemporaneously with the generation and transmission of the notification, method **500** includes signaling the first communication network to send a page to the second phone number over the first communication network (block **516**). The signaling is indicated as a page trigger that is sent to the first wireless network at time T=s6. The page is sent to the WCD **102** from the first wireless network and received at time T=t6. The page is accepted and radio connection establishment is performed at T=t7. Method **500** finally includes forwarding (at time T=s7) the incoming call to the second phone number via the first communication network (block **518**). In response to the WCD **102** accepting the page, the first wireless service connects the incoming call to the first modem, at time T=t8.

In the flow charts of FIGS. **4** and **5** presented herein, certain processes of the methods can be combined, performed simultaneously or in a different order, or perhaps omitted, without deviating from the spirit and scope of the described innovation. While the method steps are described and illustrated in a particular sequence, use of a specific sequence of steps is not meant to imply any limitations on the innovation. Changes may be made with regards to the sequence of steps without departing from the spirit or scope of the present innovation. Use of a particular sequence is therefore, not to be taken in a limiting sense, and the scope of the present innovation is defined only by the appended claims.

An example scenario in which the features of the disclosure can be advantageously implemented is now presented with specific reference to FIG. **6**. Within this example, a user mobile (cellular) device operates in both 4G LTE and CDMA 1xRTT, and includes two separate modems that support communication via the respective technology. The user mobile device can be simultaneously connected via both 4G LTE and CDMA 1xRTT, and the processes involved in managing the various activities for each radio connection independently (e.g., scanning, monitoring of control and broadcast info, and cell change/reselection) causes an excessive drain on the device's power. Additionally, the user mobile device can continually drain power even when no calls are being received by the device. Within the example scenario, the user of the mobile device registers with or activates a user account at a communication service that supports voice call forwarding and/or redirection, such as Google Voice™, for example. This registration occurs at some earlier time, which is indicated as T=−t2 at the mobile device and T=−s2 at the communication service. In one embodiment, the user also registers with or establishes a user account with a messaging service, such as Google Talk®, as one example. Following activation of the user accounts, the user registers the mobile device number with the user account established with the communication service, as indicated at time T=−t1, −s1. As one additional pre-requisite to the implementation of the disclosure, the user is assigned a second phone number (independent of the cellular phone number), which can then be used by the user for all voice and SMS communication. The communication service receives and processes calls placed to the second phone number.

When the mobile device is later connected to the Internet, via a WiFi connection using the second modem of the device, the mobile device registers with the server of the communication service, at time T=t0, s0. The connection can be established indirectly through the messaging service, in one or more embodiments where the two services are linked. The mobile device then places on or more of the cellular modems (e.g., 2G/3G/4G, etc.) into a sleep mode, and then conducts all data activity over the alternate Internet connection (using the

WiFi modem connection). This series of actions occurs at time T=t3, with optional processes occurring at time T=t1 (confirming WiFi connection to communication service) and T=t2 (sending a registration signal or ping to the wireless network, if the network is accessible). Between times T=t3 and t4, the mobile device monitors for a notification and also periodically awakens the cellular modem and exchange required "timing" parameters.

The communication service then receives an incoming call at time T=s3 and forwards a notification of the incoming call at time T=s4 to the mobile device over the WiFi network. The mobile device receives the notification at time T=t4 and awakens the cellular modem at time T=t5. Concurrently with the notification, the communication service also forwards a page trigger to the wireless network subscribed to by the mobile device, which triggers the network to generate and issue a page to the mobile device. The mobile device then receives the page at time T=t6. The communication service also forwards the call to the mobile device's phone number at time T=s7. The user of the mobile device can accept the page (T=t7) and subsequently receives the call via the cellular modem at time T=t8.

The above described aspects of the disclosure can also be used to address power consumption issue with multiple cellular RATs being simultaneously active on the mobile device. For example, when an LTE/1x device is in LTE coverage, the device registers itself with the communication service and conducts all data activity over the LTE connection. The mobile device also enters into a special mode for 1xRTT where the device performs a significant number of activities related to 1xRTT less frequently (e.g., paging monitoring, measurements, and cell selection/reselection). Then, if a call is placed to the second phone number at the communication service, the mobile device receives an incoming call indication, which is sent by the server of the communication service over the LTE connection, and the device reverts back to normal 1xRTT operation.

FIG. **7** illustrates a dual user device communication environment **700** in which a second user device is provided to enable performance of a data session with the messaging service and receive call-redirection from the communication service **160** while the first modem **120** of the WCD **102** is in a sleep state. In FIG. **7**, which is an alternate embodiment to FIG. **1**, the majority of the components of the different primary devices are similar to those presented in FIGS. **1** and **2**. Thus the description of FIG. **7** will focus mainly on those newly added components and, in particular, the components and interconnectivity of second user device **702**. As shown, second user device **702** includes processor **705**, which is coupled to memory **710**, short range communication module **720**, third modem **730**, user interface **740**, and proximity detection module **750**. Memory **710** includes VoIP services application **714**, messaging and communication services module **716**, and client server protocol (C.S.P) application **718**. Messaging and communication services module **716**, and C.S.P. application **718** provide code that executes on processor **705** to implement or control server of the functional features described herein that occur at or on second user device **702**. Third modem **730** operates according to a third communication protocol **732**, which can be similar to second communication protocol **132**, for example, and third modem **730** enables communicative access to and data and voice exchange with second communication network **170**. User interface **740** includes a messaging interface **742** that provides content **744** and in certain use cases, one or more notifications **746**. Proximity detection module **750** enables second user device **702** to determine a relative proximity of WCD **102** to second user device **702** to determined when to implement certain of the features of the alternate embodiment. Proximity detection module **750** can include a GPS module **752** or other form of position detection modules. Proximity detection module **750** can also include a threshold proximity value **754**. In the described embodiments, both WCD **102** and second user device **702** are controlled by the same user **148**. To complement the functionality of proximity detection and messaging exchange, WCD **102** is configured with C.S.P. application **728** and short range communication module **724**. WCD **102** and second user device **702** communicate via respective short range communication modules **720**, **722** over an established short range communication channel **724**.

As one additional aspect of this alternate embodiment, the communication service **160** is configured to recognize when the user **148** of WCD **102** is signed-in and is attentive to a connected second user device **702** that is in communicative proximity to the WCD **102**. To support the functional features of the communication service **160** in this alternate embodiment, communication service **160** is configured with additional functional components. As provided by FIG. **3**, communication service **160** includes a call redirection utility **328** that includes a connection quality parameter **364**, to determine when or whether the IP connection has at least a threshold quality to connect an incoming call as a VoIP call, proximity parameter **366**, to track a proximity of the WCD **102** to the second user device **702**, and a hand-off utility **368**, to identify when to handoff the call as a VoIP call versus forwarding over the first network for completion as a cellular call following device notification. Communication service **160** also includes primary device identifier **360**, which can be synonymous with the device's registered phone number, and a user activeness monitor **362**, which tracks when a user **148** of the second user device **702** is present and/or interactive with the second user device **702**. These components are shown in dashed boxes to indicate that they are optional within the above described advanced notification embodiments that do not necessarily require a second user device or include call redirection.

In this alternate embodiment, the WCD **102** operates as the primary communication device, and includes one or both of cellular modem (first modem **120**) and/or WiFi modem (second modem **130**). One or both of these modems **120**/**130** can be shut down or put in sleep mode, while data traffic communicated over the second communication network **170** (which can be another wireless network, in one embodiment) is diverted or sent directly to the second user device **702**. Accordingly, power and data consumption are reduced on the primary communication device, while the user **148** is able to monitor, receive, and/or interact with content, notifications, and portable apps that the user would otherwise receive and interact with on the primary device. As one aspect, the second user device **702** is assumed to have acceptable power and data consumption characteristics, although there is no requirement that this be less than that of the primary device. Also, the second user device **702** can be connected to the second network via a wireless connection or a direct wireless connection in alternate embodiments.

One facilitator of this dual user device implementation is the portability and seamlessness of multi-platform Apps, such as Google® Apps, which can be run on a plurality of different devices. Thus, as one example, the second user device **702** can be a personal computer or an interactive television having a robust Internet or landline phone connection. With this specific implementation, and others, an additional aspect of the disclosure can involve configuring the

communication service **160** to provide call redirection, whereby an incoming communication **156** that would otherwise be routed to the WCD **102** can instead be routed to the second user device **702** when specific conditions are in play. Among these specific conditions are the following: (a) the first modem **120** is in the sleep mode; (b) the WCD **102** is proximal to the second user device **702**; (c) the second user device **702** is actively running a messaging application that connects to the communication service **160** and is able to provide real-time information about the location status of the WCD **102** relative to the second user device **702**. Thus, according to the described embodiment, the second user device **702** would stand in to receive incoming communications **156** for the WCD **102** until the communication service **160** detects or is made aware of a termination of call redirecting (TCR) condition. Possible examples of a TCR condition includes detecting that the user is no longer attentive to the second user device, which can be inferred by one or more of: (i) user log-off from the second user device **702**, (ii) a prolonged lack-of-interaction; (iii) lack of second user device presence, as detected through a proximity or image-based detection system; (iv) movement of the primary device away from the second user device. In one embodiment, the movement of the primary device can be detected by a user wearable device **286** that loses Bluetooth or similar short-range connectivity outside of a proximity threshold. In another embodiment, the movement and/or relative locations of the two devices can be determined via triangulation and/or global positioning system (GPS) location evaluation. The presence of any of the possible CRT conditions would trigger at least one of the communication service **160**, the second user device **702**, or the WCD **102** to alert the WCD to awaken the first modem(s) **120**/**130** within the WCD **102** in order to minimize any perceived loss in connectivity with the various communication networks.

According to one aspect, in order to put the cellular modem (first modem **120**) on the WCD **102** into sleep mode when the user signs in to the messaging service via the messaging application executing on the second user device **702**, an indication is provided to the WCD **102** when the user **148** signs in to the messaging application **742** on the second user device **702**. In one embodiment, this indication can be provided using a client server protocol (C.S.P.) module that executes on and communicates between the WCD **102** and the second user device **702** over a short range low power radio technology signal **770**. Possible examples of the short range low power radio technology signal **770** includes but is not limited to WiFi, Bluetooth, IR, which are respectively enabled via corresponding communication mechanisms **240** available on the two devices **102**/**702**. When the user signs in to the user account on the messaging service via the second user device **702**, the secondary device sends a notification of the "signed-in and active" status to the WCD **102**. The WCD **102** then places its cellular modem **120** (and, in one embodiment, most other functionality in the device) to sleep, conserving power. The WCD **102** then only monitors the link to the second user device **702** for an indication that a trigger event or condition has occurred that requires the WCD **102** to exit sleep mode. According to one aspect of the disclosure, while in sleep mode, the WCD **102** either does not monitor cellular signals and pages, or monitors them very infrequently, thus conserving power at the WCD **102**.

According to one or more alternate embodiments, the at least one trigger event or condition can include at least one of: (a) detection of a termination of the close range communication channel; (b) receipt of a notification of an incoming communication being forwarded for completion over the first network; (c) detection of a termination of the active running of the messaging application at the second user device **702**; (d) receipt of a user-inactive notification indicating that a user **148** is no longer attentive to the second user device **702**; (e) detecting separation of the WCD **102** beyond a proximity threshold range of the second user device **702**; (f) detecting separation of a first user wearable device **286** from within a proximity range of the second user device **702**.

According to another aspect, when the user **148** is signed in via the second user device **702** and the WCD **102** is in sleep mode, incoming calls at the communication service **160** are forwarded to and received on the second user device **702**. As an example, and without limitation on the disclosure, incoming calls can be delivered to the second user device **702** as VoIP calls **756**. When the user **148** needs to move away from the second user device **702** while on a call (e.g., user needs to shut down his computer, operating as the second user device **702**, and leave his home or office), the user **148** is provided a selectable option, via the messaging application user interface (UI) or the VoIP UI, to trigger a call transfer feature on the second device, utilizing the functionality of the C.S.P. application **720**. Activation of the call transfer feature causes the second user device **702** to perform the following functions (a) send an indication to the WCD **102** to exit sleep mode, (b) set up a 3-way call by adding the WCD **102** to the ongoing call (via one of VoIP or cellular modem, in alternate embodiments), and (c) in response to completion of the call connection to the WCD **102**, drop the call at the second user device **702**.

It is appreciated that the diversion of data traffic to the second user device **702** can be performed using any known technique. In one embodiment, a computer can be set up to allow a user to mirror applications and/or activities running on the user's mobile device (WCD **102**) onto the computer's browser. It is similarly possible to transfer an ongoing YouTube session from the WCD **102** to the second user device **702**, as one example implementation.

FIGS. **8**-**12** are flow charts respectively illustrating the processes performed by each of the three primary devices in the above described dual-user device environment of FIG. **7**. Each of the methods **800**, **900**, **1000**, **1100**, and **1200** are completed by device execution of one or more associated code segments of one or more executable utilities at the specific device on which the method is implemented. Dashed boxes within the various flow charts indicate processes that are optional (i.e., can be included or excluded) in the particular method.

Abbreviation Problem: PDSC in FIG. **8**, and PSDC and PSCD Below are all Undefined. Should These be PDS?

FIG. **8** illustrates various aspects of the method by which the communication device (WCD **102**) implements the first user device-side functions of the disclosure in the dual user device environment of FIG. **7**, according to one embodiment. Method **800** provides a process for minimizing power consumption in WCD that includes at least a first modem and a second modem, each supporting a connection to at least one communication network. Method **800** begins at start block and proceeds to block **802** at which WCD establishes a communication channel between the messaging application and communication service over the second communication network. Method **800** then includes detecting communicative access via the first PSCD and the second PSDC module of respective user devices (block **804**). Method **800** also includes receiving, via a client server protocol (CSP) executing on the communication device, information that indicates that a second user device in proximity to the communication device is actively running a messaging application that estab-

lishes an active communication channel with a communication service responsible for routing incoming voice and data communication intended to be communicated to the first user device via a first communication network (block **806**). Method **800** further includes establishing a short range communication between the WCD and the second user device (block **808**). Following the receipt of the information and the establishment of the short range communication, method **800** includes initiating a power saving mode and placing at least the first modem in a sleep state (block **810**). As provided at block **812**, method can optionally include periodically powering on the components of the first modem to exchange parameters with the first wireless network required to maintain a ready state of the first modem. At block **814**, method **800** includes initiating monitoring protocol for receipt or detection of one or more trigger events. In one embodiment, the monitoring continues while the short range communication channel remains open with the second user device. Method **800** then includes determining at decision block **816** where at least one trigger event is detected or notification of such an event is received. In response to at least one subsequent trigger event being detected or received, method **800** includes awakening the first modem to an active state to enable use of the first modem to complete communication over the first communication network. Method can then optionally include detecting a new power conservation trigger event at WCD (block **820**) and responding by repeating the sequence of processes of method **800**.

Method **900** of FIG. **9** provides additional details of the events that triggers the awakening of the first modem at WCD after the first modem is place in the sleep state. Following start block, method **900** includes monitoring the closeness of the second user device to the WCD (block **902**) and determining at block **904** whether the devices have moved out of a proximity threshold range from each other. In one embodiment, the proximity threshold range can be defined as a particular distance (e.g., 30 feet) or a distance at which a signal quality level for the established short range communication terminates or falls below a signal strength level. Other definitions of this value are supported in various alternate embodiments. Assuming the devices have not moved out of the proximity threshold range, method **900** includes determining at block **906** whether a notification has been received indicating the messaging application on the second user device is inactive or has been signed out of. If no such notification is received, method **900** further includes determining at block **908** whether a notification has been received of the initiation of a call transfer by the second user device. In response to any of the determinations (block **904**, **906**, and **908**) yielding a positive response (YES), method **900** includes triggering the awakening of the first modem to an active state (block **910**). The determinations of blocks **904**, **906** and **908** can be performed in any order. When none of the three determinations yield a positive response (i.e., all yield a NO answer), then method **900** returns to block **902**.

FIG. **10** illustrates the method by which the call redirection is established at the WCD, according to one embodiment. Method **1000** begins at start block and proceeds to block **1002** at which WCD detects the second user device is within the proximity threshold range of the WCD. Method **1000** then includes identifying that the second user device is a pre-registered call-redirection device with the communication service (block **1004**). Method **1000** further includes forwarding a call-redirection signal to the communication service to trigger implementation at the communication service of the call redirection to the second user device (block **1006**). Method **1000** then includes placing the first modem in a sleep state (block **1008**). Once the modem is in the sleep state, method **1000** includes periodically placing the first modem in an active state in order to exchange "connection ready" parameters with the first communication network that are required to maintain the first modem in a ready state for quickly establishing a communication channel with the first communication network (block **1010**). Method **1000** then includes determining at block **1012** whether a notification is received of a trigger event or whether a trigger event is detected. In response to detection or receipt of notification of a trigger condition, method **1000** includes placing the first modem in an active state to enable receipt of a page corresponding to the incoming communication via the first modem (block **1014**). Method **1000** then ends. At decision block **1012**, when no notification or detection of a trigger event occurs, method **1000** returns to block **1010**.

The flow chart of FIG. **11** illustrates various aspects of the method by which the second user device **702** implements the second device-side functions of the disclosure in the dual user device environment of FIG. **7**, according to one embodiment. Specifically, FIG. **11** provides several of the processes of the method **1100** by which the second user device facilitates the power saving features of the WCD, according to one or more embodiments. Following the start block, method **1100** includes connecting a messaging application to a user account of a communication and/or messaging service. Method **1100** then includes detecting that the WCD is in proximity range and has the messaging application active on the WCD (block **1104**). As an extension of this feature, method **1100** further provides establishing a short range communication channel with the WCD. At block **1106**, method **1100** includes setting the user account status to indicate proximity of the WCD and to trigger issuance of a notification to the WCD of the active messaging session on the second user device. In one embodiment, method **100** can further include suspending the messaging session at the WCD. In one optional embodiment, method **1100** includes mirroring applications and activities running on the WCD onto a browser application of the electronic device (block **1108**). In one embodiment, a user interface (UI) cloning module generates a clone of the executing applications of the WCD on the electronic device in response to establishing the short range communication with the WCD while the WCD is in proximity to the electronic device. At block **1110**, method **1100** includes monitoring (a) the closeness of the WCD and comparing against the threshold proximity range and/or (b) for receipt of an incoming signal indicating call redirection is being performed to the second user device.

At decision block **1112**, method includes determining whether the WCD moves out of the proximity threshold range. In response to the WCD moving out of the proximity threshold range, method **1100** includes sending a signal to the communication service to cancel the call redirection (block **1114**). When the messaging service at the WCD was also paused or terminated, method **1100** can also include cancelling suspension of the messaging service at the WCD. Moving to decision block **1116**, following a negative response at block **1112**, method **1100** includes a determination of whether a call redirection signal is received. In response to receipt of the call redirection signal, method **1100** includes configuring the second user device to accept the call redirection and handle the call as a voice-over-IP (VoIP) call (block **1118**). Specifically, method **1100** includes accepting the call re-direction and handling a call associated with the call re-direction as a Voice over IP (VOIP) call received over the data communication network.

At decision block **1120**, method **1100** includes determining if a trigger event is detected or if a call transfer is initiated at the second user device. In response to an occurrence of one of the two conditions at block **1120**, method **1100** includes: signaling the WCD to place the call receiving modem in an active state (block **1122**); initiate a three way call connection with the WCD (block **1124**); and in response to completion of the three way call connection with the WCD, transfer the VOIP call to the WCD (block **1126**). Accordingly, the WCD is pre-configured to respond to receipt of the signal by placing the call-receiving modem into an active state if the call-receiving modem is in a sleep state. When no trigger event is detected (block **1120**) and/or when no call redirection signal is received (block **1116**), method **1100** cycles back to block **1110**.

FIG. **12** is mislabeled in the figure as FIG. **10**.

FIG. **12** presents various aspects of the method by which the communication service **160** implements call redirection to a second user device **702** for incoming calls directed to a first user device (WCD **102**) in the dual user device environment of FIG. **7**, according to one embodiment. Following start block, method **1200** includes identifying when messaging applications of both the first WCD and the second electronic device are communicatively connected to a same user account of the communication service, with at least the second electronic device having an active messaging session (block **1202**). Method **1200** then includes updating a call redirect setting at the communication service for incoming calls to the WCD to redirect to the second user device (block **1204**). According to one embodiment, method **1200** can include: receiving a signal from one of the first WCD and the second electronic device to establish the second electronic device as the active device for the user account; and in response to receiving the signal, updating a redirect setting of a call routing status of the user account to on, which causes the communication service to switch from routing incoming calls to the first WCD over the first communication interface to re-directing the incoming calls to the second electronic device.

Method **1200** also includes forwarding a sleep notification to the WCD (block **1206**). Method **1200** then includes diverting data communication and messaging traffic to the second electronic device (block **1208**) rather than sending the data and messaging traffic to the WCD. At decision block **1210** method includes determining whether a notification of a trigger event has been received from either of the user devices or if the ongoing messaging session is terminated at the second user device. When trigger condition or messaging session termination is recorded at the WCD, method **1200** includes a next determination whether an incoming call is received for the phone number assigned to the user account. Method **1200** can also optionally include forwarding a "wake-up" notification signal to the WCD to re-activate the first modem from a sleep state (block **1214**). At block **1216**, method **1200** includes generating and transmitting a notification indicating that the call is being forwarded to the WCD over the first communication network. According to one embodiment, an advance notification of incoming call (ANIC) utility executes on the processor of the communication service and configures the communication service to, in response to the call routing status not having the redirect setting set to on: generate a notification indicating that the incoming call is going to be forwarded to a second phone number associated with the first WCD; transmit the notification to the first WCD over the second communication interface. Following method **1200** includes forwarding the call page and the incoming call to the second phone number of the WCD via the normal call forwarding channels over the first communication network (block **1218**).

From block **1210**, when the determination results in a negative response, method **1200** can also include a determination at block **1220** whether an incoming call is received for the phone number assigned to the user account. In response to receipt of the incoming call, method **1200** can optionally include evaluating a robustness of the connection with the second user device to determine if the call connection is robust enough to support a voice call (block **1222**). Then, at block **1224**, method includes re-directing voice calls to the second user device. In one or more embodiments, the re-direction is implemented only in response to the connection with the electronic device being evaluated as having a desired robustness. However, in one alternate embodiment, which eliminates block **1222**, method **1200** would include: in response to receiving an incoming call directed to a phone number associated with the user account while the re-direct setting is set to on, autonomously re-direct the incoming call to the second electronic device for completion as a Voice over IP (VOIP) call.

The disclosure thus provides a system for delivery of an early notification over a non-operator-owned communication path such as a WiFi network. The user of the WCD is alerted via the active WiFi or Ethernet connection of the incoming call and by monitoring the established communication channel, the subscriber device can awake the cellular modem in time to receive the incoming cellular call before the call is sent to voicemail. The effect of the placement of the modem into the sleep state is a reduction in power and data consumption that would otherwise occur on a primary communication device modem. However, the other aspects of configuring the modem to register with and periodically checking into the cellular network, even while in the sleep mode, enable the user device to be sufficiently connected and reachable at all times on the primary communication device modem. Thus, the WCD is able to present the appearance of uninterrupted connectivity, while reducing power consumption and extending battery life.

As will be appreciated by one skilled in the art, embodiments of the present innovation may be embodied as a system, device, and/or method. Accordingly, embodiments of the present innovation may take the form of an entirely hardware embodiment or an embodiment combining software and hardware embodiments that may all generally be referred to herein as a "circuit," "module" or "system."

Aspects of the present innovation are described below with reference to flowchart illustrations and/or block diagrams of methods, apparatus (systems) and computer program products according to embodiments of the innovation. It will be understood that each block of the flowchart illustrations and/or block diagrams, and combinations of blocks in the flowchart illustrations and/or block diagrams, can be implemented by computer program instructions. These computer program instructions may be provided to a processor of a general purpose computer, special purpose computer, or other programmable data processing apparatus to produce a machine, such that the instructions, which execute via the processor of the computer or other programmable data processing apparatus, create means for implementing the functions/acts specified in the flowchart and/or block diagram block or blocks.

While the innovation has been described with reference to exemplary embodiments, it will be understood by those skilled in the art that various changes may be made and equivalents may be substituted for elements thereof without

departing from the scope of the innovation. In addition, many modifications may be made to adapt a particular system, device or component thereof to the teachings of the innovation without departing from the essential scope thereof. Therefore, it is intended that the innovation not be limited to the particular embodiments disclosed for carrying out this innovation, but that the innovation will include all embodiments falling within the scope of the appended claims. Moreover, the use of the terms first, second, etc. do not denote any order or importance, but rather the terms first, second, etc. are used to distinguish one element from another.

The terminology used herein is for the purpose of describing particular embodiments only and is not intended to be limiting of the innovation. As used herein, the singular forms "a", "an" and "the" are intended to include the plural forms as well, unless the context clearly indicates otherwise. It will be further understood that the terms "comprises" and/or "comprising," when used in this specification, specify the presence of stated features, integers, steps, operations, elements, and/or components, but do not preclude the presence or addition of one or more other features, integers, steps, operations, elements, components, and/or groups thereof.

The corresponding structures, materials, acts, and equivalents of all means or step plus function elements in the claims below are intended to include any structure, material, or act for performing the function in combination with other claimed elements as specifically claimed. The description of the present innovation has been presented for purposes of illustration and description, but is not intended to be exhaustive or limited to the innovation in the form disclosed. Many modifications and variations will be apparent to those of ordinary skill in the art without departing from the scope and spirit of the innovation. The embodiment was chosen and described in order to best explain the principles of the innovation and the practical application, and to enable others of ordinary skill in the art to understand the innovation for various embodiments with various modifications as are suited to the particular use contemplated.

What is claimed is:

1. A method for minimizing power consumption in a communication device that includes at least a first modem and a second modem, each supporting a connection to at least one communication network, the method comprising:

receiving, via a client server protocol (CSP) executing on the communication device, information that indicates that a second user device in proximity to the communication device is actively running a messaging application that establishes an active communication channel with a communication service responsible for routing incoming voice and data communication intended to be communicated to the first user device via a first communication network;

establishing a short range communication between the communication device and the second user device;

in response to receiving the information and establishing the short range communication, placing at least the first modem in a sleep state; and

in response to at least one subsequent trigger event, awakening the first modem to an active state to enable use of the first modem to complete communication over the first communication network.

2. The method of claim **1**, further comprising:

detecting a closeness of the second user device using a first proximity detection and signaling (PDS) module of the communication device;

monitoring the closeness of the second user device following the placing of the at least the first modem in the sleep state; and

triggering the awakening of the first modem, in response to the second user device falling out of a proximity range to the communication device.

3. The method of claim **1**, wherein the receiving further comprises:

when a user signs into a user account for a messaging application at the communication service, from another device that is in proximate range of the communication device, receiving an indication of a user signed-in status at the communication device; and

initiating a power saving mode at the communication device in response to receipt of the indication;

wherein the indication is provided by the CSP, which executes on and communicates between the communication device and the second user device over a short range low power radio technology signal.

4. The method of claim **3**, further comprising monitoring a link established with short range low power radio technology signal to the second user device for a subsequent indication that a trigger event has occurred that requires the communication device to cause the first modem to exit the sleep mode.

5. The method of claim **1**, wherein the at least one subsequent trigger event comprises at least one of: (a) detection of a termination of the close range communication; (b) receipt of a notification of an incoming communication being forwarded for completion over the first network; (c) detection of a termination of the active running of the messaging application at the second user device; (d) receipt of a user-inactive notification indicating that a user is no longer attentive to the second user device; (e) detecting separation of the communication device beyond a proximity threshold range of the second user device; (f) detecting separation of a first user wearable device from within a proximity threshold range of the second user device; or (g) receipt of a message from the second user device indicating initiation of a procedure on the second device to transfer communication to the communication device.

6. The method of claim **1**, wherein prior to placing at least the first modem in a sleep state, the method further comprises:

detecting communicative access via the short range communication technology to the second user device; and

identifying that the second user device is a pre-registered call-redirection device with the communication service, wherein the call-redirection device receives an incoming communication intended to be routed via the first network to the first user device while the second user device is within an established proximity threshold range of the first user device and has a corresponding messaging application set for open access to the communication service.

7. The method of claim **6**, further comprising:

forwarding a call-redirection signal to the communication service to trigger implementation at the communication service of the call redirection to the second user device; and

periodically placing the first modem in an active state in order to exchange parameters with the first communication network that are required to maintain the first modem in a ready state for quickly establishing a communication channel with the first communication network.

8. The method of claim **1**, wherein:

placing the first modem into the sleep state comprises at least one of (a) turning off power to the first modem, (b)

removing power from one or more power consuming components of the first modem, (c) turning off specific power consuming components of the first modem, (d) intermittently providing power to a subset of components of the first modem that are required to periodically transmit registration parameters to the first wireless network and exchange timing data with a network tower for uplink and downlink communication, (e) placing the first modem in a low power state in which the first modem consumes a limited amount of power but retains operational readiness to enable a quick response to receipt of the incoming communication, or (f) placing the first modem in a state in which the first modem monitors a signal of the first communication network less frequently than the frequency of monitoring of the signal when the first modem is in an active state.

9. The method of claim **1**, wherein the trigger event is receipt of a notification at the second modem of an incoming communication to be routed via the first communication network, and the awakening of the first modem comprises:

in response to receipt, at the second modem, of the notification, awakening the first modem to an active state to enable receipt of a page corresponding to the incoming communication via the first modem.

10. A wireless communication device comprising:

a first wireless modem that enables the wireless communication device (WCD) to interface with a first wireless network and perform wireless communication exchange via a first communication channel;

a second wireless modem that enables the WCD to interface with a second wireless network and perform wireless communication exchange via a second communication channel;

at least one processor coupled to the first wireless modem and the second wireless modem:

a client server protocol (CSP) executing on the communication device and which receives information that indicates that a second user device in proximity to the communication device is actively running a messaging application that establishes an active communication channel with a communication service responsible for routing incoming voice and data communication intended to be communicated to the first user device via a first communication network;

a short range communication component that establishes a short range communication between the communication device and a second short range communication device of the second user device to track the proximity of the communication device to the second user device;

a communication and power management (CPM) utility that executes on the processor and configures the WCD to:

in response to receiving the information and establishing the short range communication, place at least the first modem in a sleep state; and

in response to at least one subsequent trigger event, awaken the first modem to an active state to enable use of the first modem to complete communication over the first wireless network.

11. The WCD of claim **10**, further comprising:

a first proximity detection and signaling (PDS) module that:

detects a closeness of the second user device to the communication device;

monitors the closeness of the second user device following the placing of the at least the first modem in the sleep state; and

triggers the awakening of the first modem in response to the second user device falling out of proximity range of the communication device.

12. The WCD of claim **10**, wherein the client sever protocol further:

receives an indication of a user signed-in status at the communication device, when a user signs into a user account for a messaging application at the communication service, from another device that is in proximate range of the communication device; and

triggers the CPM utility to initiate a power saving mode at the communication device in response to receipt of the indication;

wherein the indication is provided by the CSP, which executes on and communicates between the communication device and the second user device over a short range low power radio technology signal.

13. The WCD of claim **10**, wherein prior to placing at least the first modem in a sleep state, the CPM utility further:

detects communicative access via the short range communication technology to the second user device;

identifies that the second user device is a pre-registered call-redirection device with the communication service, wherein the call-redirection device receives an incoming communication intended to be routed via the first network to the first user device while the second user device is within an established proximity threshold range of the first user device and has a corresponding messaging application set for open access to the communication service.

14. The WCD of claim **10**, wherein the CPM utility further configures the device to:

forward a call-redirection signal to the communication service to trigger implementation at the communication service of the call redirection to the second user device; and

periodically place the first modem in an active state in order to exchange parameters with the first communication network that are required to maintain the first modem in a ready state for quickly establishing a communication channel with the first communication network.

15. An electronic device comprising:

a modem utilized by the electronic device to interface with a data communication network and exchange voice and data communication with a communication service that is configured to provide call redirection services for incoming calls to a wireless communication device (WCD);

a short range communication component that establishes a short range communication between the electronic device and the WCD when the WCD is in proximity of the electronic device;

a proximity detection and signaling (PDS) module that monitors the proximity of the WCD to the electronic device;

a client server protocol that supports Internet protocol (IP) data communication services via at least one IP network and enables the electronic device to provide an active portal to a user account of a messaging service that is also provided on the WCD, wherein the electronic device enables user log in to the user account via a messaging application to provide an active messaging session; and

at least one processor coupled to the modem, the short range communication component and the PDS module and which executes program code, including program

code of the CSP and the messaging application to configure the electronic device to:

connect to the user account at the communication service;

trigger the communication service to issue a notification to the WCD to indicate that the messaging session is active on the electronic device;

identify within the trigger to the communication service that the electronic device is within proximity of the WCD;

in response to receipt of an incoming signal indicating a call re-direction is being made to the electronic device:

accept the call re-direction; and

handle a call associated with the call re-direction as a Voice over IP (VOIP) call received over the data communication network.

16. The electronic device of claim **15**, further comprising:

in response to identifying one of a plurality of trigger events occurring with one of the electronic device, the WCD, and the messaging service, the CSP configures the electronic device to:

signal the WCD to place a call-receiving modem into an active state, wherein the WCD is pre-configured to respond to receipt of the signal by placing the call-receiving modem into an active state if the call-receiving modem is in a sleep state;

initiate a three way call connection with the WCD; and

in response to completion of the three way call connection with the WCD, transfer the VOIP call to the WCD.

17. The electronic device of claim **15**, wherein the PDS module:

triggers the short range communication component to establish a close range communication channel with a next short range communication component of the WCD to track the proximity of the WCD to the electronic device;

detects when the proximity of the WCD to the electronic device falls outside of a threshold proximity; and

in response to detecting that the proximity of the WCD to the electronic device falls outside of a threshold proximity, forwards a signal to the messaging service that the electronic device is no longer within proximity to the WCD.

18. The electronic device of claim **15**, wherein the CSP configures the electronic device to:

signal to the WCD that the electronic device has an active messaging session with the communication service; and

signal at least one of the WCD and the communication service when a trigger event is detected from among (i) passage of a period of user inactivity with one of the messaging application and the electronic device, (ii) loss of short range communication with the WCD, and (iii) loss of the active messaging communication session.

19. The electronic device of claim **15**, further comprising a user interface (UI) cloning module that enables the electronic device to mirror applications and activities running on the WCD onto a browser application of the electronic device, wherein the UI cloning module generates a clone of the executing applications of the WCD on the electronic device in response to establishing the short range communication with the WCD while the WCD is in proximity to the electronic device.

20. The electronic device of claim **15**, further comprising a call transfer module within a VOIP application that can be triggered by a user of the electronic device to initiate transfer of an ongoing call from the electronic device to the WCD when the call was originally intended for the WCD and redirected to the electronic device.

21. The electronic device of claim **16**, wherein the PDS module: determines a current position of the electronic device; calculates a relative proximity of the WCD to the electronic device; and transmits an indication to a user account at the messaging service indicating when the electronic device is in proximity of the WCD.

22. A communication service comprising:

a processor;

a first communication interface enabling communication with user devices via a first communication network that supports routing of voice calls to a first wireless communication device (WCD) associated with a user account maintained at the communication service;

a second communication interface enabling communication with at least the first WCD and a second electronic device, via a second communication network;

a call re-direction utility that executes on the processor and which configures the communication service to:

identify when messaging applications of both the first WCD and the second electronic device are communicatively connected to a same user account of the communication service, with at least the second electronic device having an active messaging session;

receive a signal from one of the first WCD and the second electronic device to establish the second electronic device as the active device for the user account;

in response to receiving the signal, updating a redirect setting of a call routing status of the user account to on, which causes the communication service to switch from routing incoming calls to the first WCD over the first communication interface to re-directing the incoming calls to the second electronic device; and

in response to receiving an incoming call directed to a phone number associated with the user account while the re-direct setting is set to on, autonomously re-direct the incoming call to the second electronic device for completion as a Voice over IP (VOIP) call.

23. The communication service of claim **22**, further comprising:

an advance notification of incoming call (ANIC) utility that executes on the processor and which configures the communication service to, in response to the call routing status not having the redirect setting set to on:

generate a notification indicating that the incoming call is going to be forwarded to a second phone number associated with the first WCD;

transmit the notification to the first WCD over the second communication interface; and

forward the incoming call to the second phone number via the first communication interface.

24. The communication service of claim **22**, wherein the call re-direction utility executes on the processor and configures the communication service to:

in response to updating the call redirection setting to on, forward a sleep notification to the WCD via the second communication interface to trigger at least a first modem of the WCD to enter into the sleep state;

subsequently divert data traffic to the electronic device via the second communication interface; and

in response to detecting that the messaging session with the second electronic device is no longer active, forwarding an awake signal notification to trigger WCD to re-activate the first modem from the sleep state.

25. The communication service of claim 22, wherein prior to autonomously redirecting the incoming call to the second electronic device, the call re-direction utility configures the commutation service to:

evaluate a robustness of a connection with the second electronic device; and

re-directing voice calls to the electronic device only in response to the connection with the electronic device being evaluated as having a desired robustness.
